(Dated: May 9nd, 2007)

Recently in Ref. [1] has been proposed a GUT model for fermion masses and mixings with spontaneously broken S_3 discrete flavor symmetry, where S_3 is the permutation group of three objects. The S_3 breaking pattern in the quark sector is not studied and need further investigation. Since in such a model the number of free parameters is greater than the number of experimental observables, an analytical fit of all the parameters is impossible. To go forward with the model building and to deal with this problem we have used a statistical analysis. We have found that S_3 is totally broken and the up-type quarks matrix is approximately diagonal while down-type quarks matrix is not symmetric and it is parametrized by three couplings, g^d , g_L^d and g_3^d . It has been found that g_L^d is slightly smaller than $g^d = 1$ and it is of order one, while $g_3^d \sim \lambda^3$ where λ is the Cabibbo angle. An analytical study of the dependence of V_{cb} and V_{ub} from the couplings g_L^d and g_3^d is also presented.

I. INTRODUCTION

In third quantization [2] we can explain the origin of the fermion families and the origin of the permutation symmetry between them. Third quantization is an extension of the quantum field theory where the fields are treated as well as particles in second quantization. Discrete flavor symmetries, like the group of permutation of three objects S_3 , are very interesting since they can naturally explain neutrino mixing angles and mass hierarchies, for instance see Ref. [3]. Some recent reviews in the study of hierarchical structure of fermion masses in the Standard Model and its extensions are reported in Ref [4]. Indications toward grand unification gauge theory

*Electronic address: stefano.morisi@mi.infn.it

(GUT), is the phenomenological tendency to unify of the gauge couplings, and the theoretical implicit possibility to explain charge quantization and anomaly cancellation. In Ref. [1] it has been proposed a model based on $E_6 \times S_3$ in order to arrange quark, lepton and neutrino masses and mixings. Minimal GUT models give strong relations between quarks and leptons Yukawa matrices. For example in minimal SO(10) models up quarks Yukawa matrix is equal to the Dirac neutrino Yukawa matrix. However quarks and neutrinos mass and mixing hierarchies are very different. In fact, neutrino oscillation data show a maximal atmospheric angle, large solar angle and θ_{13} close to zero, see Ref. [5]. In contrast the greatest angle in the quark sector, namely the Cabibbo one, is smaller than the corresponding leptonic mixing angle, see Ref. [6]. Phenomenological quark/lepton difference seems in contrast with GUT features. Even though in E_6 models it is possible to make a distinction between charged fermions and neutrinos as showed in Ref. [1]. Authors evidenced this possibility by means of the two standard model singlets contained in E_6 . In such a model quarks Yukawas only emerge after S_3 symmetry is broken by not renormalizable dimension five operators, while renormalizable operators only contribute to Dirac neutrino Yukawas. However the study of S_3 breaking pattern in the quark sector has not been accomplished in Ref. [1] and it will be performed in this paper.

We will show that in our model up and down-type quark mass matrices are parametrized both by five complex couplings and three real parameters. Since the number of free parameters in the quark sector of the model is larger than the number of experimental data, a direct fit is impossible. One possibility to deal with this problem, is comparing the theoretical expectations with the experimental data by means of a montecarlo method (see Ref. [7]) that assigns a probability weight to points in the parameter space of the model according to a goodness of fit criterion. In this way we find the statistically preferred textures of the mass matrices for up and down-type quarks. In particular we select a large number of points in the parameters space initially uniformed distributed. After applying the experimental constrains, not all the selected points agree with data. To apply the experimental constrains it is been used the χ^2 function defined as below

$$\chi^2(O^{th}) = \sum_i \left(\frac{O_i^{th} - O_i^{exp}}{\sigma_i^{exp}} \right)^2 \quad (1)$$

where O_i^{exp} and σ_i^{exp} are respectively the experimental data and their standard deviations while O_i^{th} are the corresponding values predicted by the model. The points in the configuration space are statistically taken with a probability proportional to $\exp(-\chi^2/2)$. After experimental constrains are applied we get a not uniform distribution in the parameters space. Regions very high populated will be interpreted statistically more probable than regions with low density population. This

method selects models statistically preferred by data giving the magnitude of the fitting parameters.

The paper is organized as follows: in section II we give the up and down quark mass matrices textures derived by $E_6 \times S_3$ model, in section III we introduce the numerical method used and we report the results, in section IV we give the conclusions.

II. S_3 SYMMETRY AND THE QUARK MASS MATRICES

The discrete group of permutation of three objects, called S_3 , contains six elements and it has four irreducible representations, namely a doublet **2**, one symmetric singlet **1** and one antisymmetric singlet **1'**, see for instance Ref. [8]. The product of two doublets is

$$\mathbf{2} \times \mathbf{2} = \mathbf{2} + \mathbf{1} + \mathbf{1}'. \quad (2)$$

In particular, if (χ_1^a, χ_2^a) and (χ_1^b, χ_2^b) are two S_3 doublets, their product is

$$\begin{aligned} \chi_D &= \frac{1}{\sqrt{2}}(\chi_2^a \chi_1^b + \chi_1^a \chi_2^b, \chi_1^a \chi_1^b - \chi_2^a \chi_2^b) \\ \chi_S &= \frac{1}{\sqrt{2}}(\chi_1^a \chi_1^b + \chi_2^a \chi_2^b) \\ \chi_A &= \frac{1}{\sqrt{2}}(\chi_2^a \chi_1^b - \chi_1^a \chi_2^b) \end{aligned}$$

where χ_D is the doublet of eq.(2) while χ_S and χ_A are respectively the symmetric and the antisymmetric singlets.

Let be ψ_1 , ψ_2 and ψ_3 three fields belonging to a triplet reducible representation **3** of S_3 . Then the triplet reducible representation decomposition is **3=2+1**:

$$\begin{aligned} \psi_S &= \frac{1}{\sqrt{3}}(\psi_1 + \psi_2 + \psi_3) \\ \psi_D &= \left(\frac{1}{\sqrt{2}}(-\psi_2 + \psi_3), \frac{1}{\sqrt{6}}(-2\psi_1 + \psi_2 + \psi_3) \right) \end{aligned} \quad (3)$$

where ψ_S is a symmetric singlet of S_3 and ψ_D is a doublet of S_3 .

In $E_6 \times S_3$ model of Ref. [1] the quarks Yukawa matrices come from dimension five operators below

$$L_{Yuk} = \sum_{i \neq j \neq k} \left(g_{ijk}^u H_u \bar{Q}_{Li} u_{Rj} \phi_k^u + g_{ijk}^d H_d \bar{Q}_{Li} d_{Rj} \phi_k^d \right) + \text{h.c.} \quad (4)$$

where $i, j, k = 1, 2, 3$, the scalar fields $\phi_i^{u,d}$ are Standard Model singlets, H_u and H_d are electroweak doublets, Q_{Li} are the left-handed fermion electroweak doublets while u_{Ri} and d_{Ri} are right-handed

fermion electroweak singlets and $g_{ijk}^{u,d}$ are S_3 tensors. We assign the left-handed fermions, the right-handed fermions and the scalar $\phi_i^{u,d}$ to triplet reducible representations of S_3 , namely

$$Q_L = (u_i, d_i)_L \sim \mathbf{3}, \quad u_{R\ i} \sim \mathbf{3}, \quad d_{R\ i} \sim \mathbf{3}, \quad \phi_i^{u,d} \sim \mathbf{3}.$$

The Higgs electroweak doublets are S_3 symmetric singlets, $H_{u,d} \sim \mathbf{1}$. With this assignment both the operators in eq. (4) transform with respect to the permutation group as follows

$$\begin{aligned} \mathbf{3}_a \times \mathbf{3}_b \times \mathbf{3}_c \times \mathbf{1} &= (\mathbf{2}_a + \mathbf{1}_a) \times (\mathbf{2}_b + \mathbf{1}_b) \times (\mathbf{2}_c + \mathbf{1}_c) \times \mathbf{1} = \\ &= (\mathbf{2}_a \times \mathbf{2}_b \times \mathbf{2}_c + \mathbf{2}_a \times \mathbf{2}_b \times \mathbf{1}_c + \mathbf{2}_a \times \mathbf{1}_b \times \mathbf{2}_c + \mathbf{1}_a \times \mathbf{2}_b \times \mathbf{2}_c + \mathbf{1}_a \times \mathbf{1}_b \times \mathbf{1}_c) \times \mathbf{1}. \end{aligned} \quad (5)$$

First four terms of five in eq.(5) contain the symmetric and the antisymmetric singlets, see eq. (2). Only symmetric singlets give S_3 invariant interactions because we have chosen the Higgs fields in symmetric singlet representation and $\mathbf{1} \times \mathbf{1}' = \mathbf{1}'$. Consequently Yukawa interactions in eq. (4) give only five terms S_3 invariant [12] both in up and down quark sectors.

The lagrangian is, see also Ref. [9],

$$\begin{aligned} L_{yuk} &= (c_1^d \bar{Q}_D d_D \phi_D + c_2^d \bar{Q}_D d_S \phi_D + c_3^d \bar{Q}_S d_D \phi_D + c_4^d \bar{Q}_D d_D \phi_S + c_5^d \bar{Q}_S d_S \phi_S) H^d \\ &+ (c_1^u \bar{Q}_D u_D \phi_D + c_2^u \bar{Q}_D u_S \phi_D + c_3^u \bar{Q}_S u_D \phi_D + c_4^u \bar{Q}_D u_D \phi_S + c_5^u \bar{Q}_S u_S \phi_S) H^u \\ &+ \text{h.c.} \end{aligned} \quad (6)$$

where Q_D , d_D , u_D , ϕ_D , Q_S , d_S , ϕ_S and u_S follow from relations in eq.(3) and $c_i^{u,d}$ are arbitrary complex constants. With the following redefinition of the complex constants

$$\begin{aligned} c_1 &= \sqrt{\frac{2}{3}} (g - g_2 - g_L - g_R + g_3) \\ c_2 &= \sqrt{\frac{2}{3}} (g - g_2 + 2 g_L - g_R - g_3) \\ c_3 &= \sqrt{\frac{2}{3}} (g - g_2 - g_L + 2 g_R - g_3) \\ c_4 &= \sqrt{\frac{2}{3}} (g + 2 g_2 - g_L - g_R - g_3) \\ c_5 &= \frac{1}{\sqrt{3}} g + 2(g_2 + g_L + g_R + g_3) \end{aligned} \quad (7)$$

and using relations in eq. (3), from eq. (6) we get the following down quarks lagrangian

$$\sum_{i \neq j \neq k} \left(g \bar{d}_L^i d_R^i H \phi_i + g_2 \bar{d}_L^i d_R^i H \phi_j + g_L \bar{d}_L^i d_R^j H \phi_i + g_R \bar{d}_L^i d_R^j H \phi_j + g_3 \bar{d}_L^i d_R^j H \phi_k \right) + \text{h.c.} \quad (8)$$

and the corresponding mass matrix is

$$\begin{aligned}
M^d = & g^d v_H^d \begin{pmatrix} v_1^d & 0 & 0 \\ 0 & v_2^d & 0 \\ 0 & 0 & v_3^d \end{pmatrix} + g_2^d v_H^d \begin{pmatrix} v_2^d + v_3^d & 0 & 0 \\ 0 & v_1^d + v_3^d & 0 \\ 0 & 0 & v_1^d + v_2^d \end{pmatrix} + \\
& + g_L^d v_H^d \begin{pmatrix} 0 & v_1^d & v_1^d \\ v_2^d & 0 & v_2^d \\ v_3^d & v_3^d & 0 \end{pmatrix} + g_R^u v_H^u \begin{pmatrix} 0 & v_2^d & v_3^d \\ v_1^d & 0 & v_3^d \\ v_1^d & v_2^d & 0 \end{pmatrix} + g_3^d v_H^d \begin{pmatrix} 0 & v_3^d & v_2^d \\ v_3^d & 0 & v_1^d \\ v_2^d & v_1^d & 0 \end{pmatrix} \quad (9)
\end{aligned}$$

where $v_i^d = \langle \phi_i^d \rangle$ and $v_H^d = \langle H^d \rangle$. We observe that M^d is parametrized by five complex coupling constants and three scalar vevs, namely 13 real parameters. Similar lagrangian and mass matrix can be obtained for up quarks.

We want to fit the hierarchies of the coupling constants g_2 , g_L , g_R and g_3 [13], then we parametrize their absolute values as power of the Cabibbo angle as below

$$g_2^{u,d} \equiv a_2^{u,d} \lambda^{t_2^{u,d}}, \quad g_L^{u,d} \equiv a_3^{u,d} \lambda^{t_L^{u,d}}, \quad g_R^{u,d} \equiv a_4^{u,d} \lambda^{t_R^{u,d}}, \quad g_3^{u,d} \equiv a_5^{u,d} \lambda^{t_3^{u,d}} \quad (10)$$

where $\lambda = 0.2$, the t exponents are free real parameters and $a_2^{u,d}$, $a_3^{u,d}$, $a_4^{u,d}$ and $a_5^{u,d}$ are complex phases.

III. THE NUMERICAL FIT

A. The method

The goal is to extract the values of $t_2^{u,d}$, $t_R^{u,d}$, $t_L^{u,d}$ and $t_3^{u,d}$ of eq. (10), namely the magnitude order of the g s couplings, and the values of the vevs of the scalars $v_1^{u,d}$, $v_2^{u,d}$ and $v_3^{u,d}$ from the experimental measurements. A direct fit of the data is not possible, since the number of free parameters in eq. (9) is much larger than the number of observables, six mass eigenvalues plus four CKM parameters. The main obstacle comes from the coefficients $a_i^{u,d}$, whose phases are not theoretically known. To cope with them, we will treat this uncertainty as a theoretical *systematic error*. Namely, we have assigned a flat probability to all the coefficients $a_i^{u,d}$ with

$$|a_i^{u,d}| = 1, \quad 0 < \arg(a_i^{u,d}) < 2\pi. \quad (11)$$

The exponents and the vevs are chosen in the ranges

$$\begin{aligned}
0 < t_2^{u,d}, t_R^{u,d}, t_L^{u,d}, t_3^{u,d} < 8, \\
0 < v_1^{u,d}, v_2^{u,d} < v_3^{u,d} = 1,
\end{aligned} \quad (12)$$

and we randomly take them with a flat distribution in logarithmic scale. $v_1^{u,d}$, $v_2^{u,d}$ and $v_3^{u,d}$ must satisfy the above constraints since (by definition) we choose the entry (3,3) of the matrices in (9) to be the largest one. For any random choice of the coefficients $a_i^{u,d}$, of the exponents t and of the vev's $v_i^{u,d}$ we respectively get two numerical matrices for the up and the down sectors. The diagonalization of these two matrices, gives six eigenvalues, corresponding to the physical up and down quark masses to be compared with the experimental values of the masses runned at the unification scale $2 \cdot 10^{16} Gev$ (see Ref. [10]) and reported in Table I. The multiplication of the two

Mass	Reference value
$m_u(\text{MeV})$	$0.8351^{+0.1636}_{-0.1700}$
$m_c(\text{MeV})$	$242.6476^{+23.5536}_{-24.7026}$
$m_t(\text{GeV})$	$75.4348^{+9.9647}_{-8.5401}$
$m_d(\text{MeV})$	$1.7372^{+0.4846}_{-0.2636}$
$m_s(\text{MeV})$	$34.5971^{+4.8857}_{-5.1971}$
$m_b(\text{GeV})$	$0.9574^{+0.0037}_{-0.0169}$

TABLE I: Quark masses runned at $2 \cdot 10^{16} Gev$ scale in nonSUSY standard model.

unitary matrices that diagonalize on the left the up and down mass matrices respectively, yields the quark mixing CKM matrix. The CKM is parametrized by the four Wolfenstein parameters λ , A , ρ and η and their experimental values (see Ref. [6]) are reported in Table II. We have collected

CKM parameter	Reference value
λ	0.2237 ± 0.0033
$ V_{cb} $	$(41.0 \pm 1.6) \times 10^{-3}$
ρ	0.225 ± 0.038
η	0.317 ± 0.041

TABLE II: CKM parameters.

a large statistical sample of events. Each one event can be compared with the experimental data through the χ^2 , namely the event is accepted with probability

$$P(O_i^{th}) = e^{-\frac{1}{2}\chi^2(O_i^{th})} \quad (13)$$

where the χ^2 is defined in eq. (1). Before applying the experimental constraints, events are homogeneously distributed in the variables $t_i^{u,d}$, $v_i^{u,d}$, and probability distributions are flat, but after applying the weight corresponding to eq. (13), only points lying in well defined regions of the space

$t_i^{u,d}$ and $v_i^{u,d}$ have a good chance to survive and the events are not uniformly distributed in the configuration space. The density is related to the probability that an event predicts masses and mixings in a range compatible with the experiments. Even if our montecarlo approach gives more predictive and accurate models, we also emphasize that one should not think these results as true experimental measurements. They only give “natural” range of values for the exponents $t_i^{u,d}$ and $v_i^{u,d}$.

B. The result

The statistical analysis gives different regions of points in the parameters space accordingly with the distribution $\exp(-\chi^2/2)$. Due to a numerical instability we are unable to compare different regions of solutions. Whatever isolated points in the configuration space are statistically disfavored since unphysical phases in eq. (10) should be tuned in order to fit the experimental data. While points in regions with high density population are statistically preferred by data as explained in the previous section and in Ref. [7].

Let us now to consider the scalar vevs obtained with the montecarlo analysis. In Fig. 1 are plotted on the left up-type quark vevs and on the right the down-type quark vevs, in particular it is plotted first generation in the y axis *vs* second generation in the x axis. The third generation of vevs are fixed to be $v_3^u = 1$ and $v_3^d = 1$. From Fig. 1 we have the bounds below

FIG. 1: Values of the VEV of the scalar $SU(2)$ singlet fields in the up on the *left* and down sectors on the *right*.

$$\begin{aligned}
10^{-6} &< v_1^u < 10^{-4} \\
2 \cdot 10^{-3} &< v_2^u < 3 \cdot 10^{-3} \\
10^{-4} &< v_1^d < 10^{-2} \\
2 \cdot 10^{-2} &< v_2^d < 6 \cdot 10^{-2}
\end{aligned}$$

in agreement with the observed mass hierarchies at the unification scale (see Table I)

$$v_1^u : v_2^u : v_3^u = m_u : m_c : m_t = \lambda^7 : \lambda^4 : 1, \quad (14)$$

$$v_1^d : v_2^d : v_3^d = m_d : m_s : m_b = \lambda^4 : \lambda^2 : 1. \quad (15)$$

Relations (14) and (15) show that in quark sector the S_3 symmetry is totally broken.

The magnitude of $g_2^{u,d}$, $g_L^{u,d}$, $g_R^{u,d}$ and $g_3^{u,d}$ are related to the ts exponents like in eq. (10). In Fig.(2) we report the montecarlo results for the ts exponents given by the statistical analysis allowed after the application of the experimental constrains eq. (13).

FIG. 2: t exponents that parametrize the magnitude of the g couplings in the general case. We have plotted the plane (t_L^d, t_R^d) , (t_L^u, t_R^u) , (t_3^u, t_3^d) and (t_2^u, t_2^d) .

From these figures it is not difficult to obtain the following bounds for the t exponents

$$\begin{aligned}
0 &< t_L^u < 8 ; 3 < t_R^u < 8, \\
4.5 &< t_3^u < 8 ; 5 < t_2^u < 8.
\end{aligned} \quad (16)$$

$$\begin{aligned}
0 < t_L^d < 1 & ; \quad 2.5 < t_R^d < 8, \\
2.5 < t_3^d < 3 & ; \quad 5 < t_2^d < 8.
\end{aligned}
\tag{17}$$

The upper bounds $t=8$ in eq. (16) and eq. (17) is the cutoff used in the montecarlo method, see eq. (12). An upper bound $t < \alpha < 8$ correspond to a g coupling lower bound, namely $|g| > \lambda^\alpha$. In the up quark sector, g_s couplings are not bounded from below since the corresponding ts exponents could be large, namely in eq. (16) all the ts exponents can be taken equal to the cutoff used in the statistical analysis. This means that all the g_s couplings in the up quark sector can be very small of order λ^8 . In contrast, in the down sector the couplings g_L^d and g_3^d are bounded from below[14]

$$|g_L^d| > \lambda, \quad |g_3^d| > \lambda^3, \tag{18}$$

while the couplings g_2^d and g_R^d in the down sector can be very small like in the up quark sector. Experimental data statistically prefer models where the absolute value of the $|g_L^d|$ coupling is large, see eq. (18). In particular $|g_L^d|$ can be close to one or to the maximal value allowed in the montecarlo analysis, see eq. (12) and it is slightly smaller than $g^d = 1$. Indeed from relations (17) and (18) the g_3^d coupling also has an upper bound, that is $|g_3^d| < \lambda^{2.5} \ll \lambda$. Therefore from the statistical analysis we get the following hierarchies between the g_s couplings

$$1 = g^u = g^d \simeq |g_L^d| \gg |g_3^d| \gg |g_2^d|, |g_R^d|, |g_2^u|, |g_L^u|, |g_R^u|, |g_3^u|. \tag{19}$$

In Table III we report a numerical example of values for the g_s coupling and for the vevs that fit good data.

up	down
$\phi_1^u/\phi_3^u = m_u/m_t$	$\phi_1^d/\phi_3^d = 0.000077$
$\phi_2^u/\phi_3^u = m_c/m_t$	$\phi_2^d/\phi_3^d = 0.054783$
$g = 1$	$g = 0.848$
$g_L \simeq 0$	$g_L = 0.305 e^{-i \ 0.02}$
$g_R \simeq 0$	$g_R = 0.002 e^{-i \ 0.12}$
$g_L \simeq 0$	$g_L = 0.009 e^{i \ 1.82}$

TABLE III: Example of set of values of g couplings and vevs that fit the data.

C. The CKM and the couplings g_L^d and g_3^d

The statistical analysis results in previous section, show that in first approximation the experimental data can be fitted only with couplings g^u , g^d , g_L^d and g_3^d couplings ($g^{u,d}$ are fixed), besides the vevs of the scalar fields. In this section we want to study the relation between the g_L^d and g_3^d and the entries of the CKM mixing matrix. Accordingly we fix the values of the scalar vevs like in eq. (14) and eq. (15). From eq. (14), eq. (15) and eq. (19) we get, up to correction of order λ^8 , the mass matrices below

$$M^u \simeq v_H^u \begin{pmatrix} \lambda^7 & 0 & 0 \\ 0 & \lambda^4 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad M^d \simeq v_H^d \begin{pmatrix} \lambda^4 & g_L^d \lambda^4 + g_3^d g_L \lambda^4 + g_3^d \lambda^2 \\ g_L^d \lambda^2 + g_3^d & \lambda^2 & g_L^d \lambda^2 + g_3^d \lambda^4 \\ g_L^d + g_3^d \lambda^2 & g_L^d + g_3^d \lambda^4 & 1 \end{pmatrix}. \quad (20)$$

The up quark mass matrix in eq. (20) is almost diagonal and the quark mixing matrix V_{CKM} is approximatively given by the unitary matrix U_d that diagonalize on the left the down quark mass matrix eq. (20), namely $U_d^\dagger M_d M_d^\dagger U_d = D_d^2$. We observe that in general the g_L^d and g_3^d are arbitrary complex variables. In order to simplify the problem, we assume g_L^d and g_3^d reals and the CKM complex phase η is not fitted.

In the standard parametrization $V_{CKM} = R_{23} R_{13} R_{12}$ where R_{ij} are rotations in the (ij) plane of θ_{ij} angles, then $|V_{cb}| \approx \sin \theta_{23}$ and $|V_{ub}| \approx \sin \theta_{13}$. From mass matrices (20) we have

$$|V_{cb}| \simeq \frac{1}{\sqrt{2}} \sqrt{1 + \frac{(1 + 2g_L^2)(\lambda^4 - 1)}{\sqrt{16g_L^3 \lambda^4 + (\lambda^4 - 1)^2 + 4g_L^4(1 - \lambda^4 + \lambda^8)}}} \quad (21)$$

where $g_L = \lambda^{t_L}$, so in first approximation $|V_{cb}|$ is only a function of the coupling g_L^d . In Fig. 3 we

FIG. 3: Plot of the function $|V_{cb}| = V_{cb}(t_L)$ and $|V_{ub}| = V_{ub}(t_3)$.

plot the function $|V_{cb}| = V_{cb}(t_L)$. We observe that when $t_L \simeq 0.5$ the corresponding $|V_{cb}|$ agree with data and $t_L \simeq 0.5$ is close to the value from the montecarlo, see in eq. (17).

Analogously we can use the remaining free parameter g_3^d to fit the $|V_{ub}|$ as below

$$|V_{ub}| \simeq \frac{1}{\sqrt{2}} \sqrt{1 + \frac{g_3^2 - 4g_3\lambda^2 - 3}{\sqrt{9 + g_3^4 + 24g_3\lambda^2 - 8g_3^3 + 2g_3^2(10\lambda^4 + 4\lambda^2 - 1)}}}. \quad (22)$$

In Fig. 3 we have plotted the function $V_{ub}(t_3)$. $|V_{ub}|$ agrees with experimental data when $t_3 \simeq 3$, in agreement with statistical analysis. $|V_{ub}|$ is approximatively only a function of g_L^d coupling. Assuming for instance $t_L = 0.55$ and $t_3 = 3.1$ in eq. (20), we have $|V_{us}| \simeq 0.21$, $|V_{ub}| \simeq 0.004$ and $|V_{cb}| \simeq 0.043$ that agree with data.

IV. CONCLUSIONS

Recently it has been proposed in Ref. [1] a model based on $E_6 \times S_3$ in order to explain fermions mass and mixing hierarchies. However a full study of S_3 breaking pattern was not accomplished. We carry out such a study. In the model of Ref. [1] quark mass terms appear as higher order dimension five operators after S_3 is broken. We have showed that in such a model quark mass matrices are parametrized by five complex couplings $g^{u,d}$, $g_2^{u,d}$, $g_L^{u,d}$, $g_R^{u,d}$, $g_3^{u,d}$ and three real parameters $v_1^{u,d}$, $v_2^{u,d}$, $v_3^{u,d}$ that are the vevs of the scalar fields that break S_3 . Even if we can assume $g^u = g^d = 1$ and $v_1^u = v_1^d = 1$, the number of free parameters in the model is larger than the number of experimental data then it is not possible to fit the parameters. To go forward we have used a numerical approach finding the statistically preferred textures of the mass matrices according to a goodness of fit criterion. We have found that the permutation symmetry S_3 is totally broken and vev hierarchies should be $v_1^{u,d} \ll v_2^{u,d} \ll v_3^{u,d}$, and data statistically prefer solutions with large $|g_L^d|$ coupling, namely slightly smaller than $g^u = 1$, and $|g_3^d| \approx \lambda^3$ while the remain couplings in up and down quark textures, are negligible and are of order λ^8 . The resulting up quark mass matrix is almost diagonal and the quarks mixing matrix is approximatively given by the down quark mass matrix that is not symmetric. The hierarchies between the yukawa couplings is

$$1 = g^u = g^d \simeq |g_L^d| \gg |g_3^d| \gg |g_2^d|, |g_R^d|, |g_L^u|, |g_R^u|, |g_3^u|. \quad (23)$$

Ultimately we have studied the relation between the couplings g_L^d , g_3^d and the CKM mixing matrix. We have found that V_{cb} is approximatively a function of g_L^d coupling and V_{ub} is approximatively a function of g_3^d coupling.

The study of the breaking pattern of the S_3 symmetry in the quark sector, gives indications to go forward in the model building. In fact recently in Ref. [11] it has been studied a model that could

explains quark, lepton and neutrino mixings and masses, making use of the montecarlo statistical analysis results reported in this paper. In particular in the model of Ref. [11] are explained the hierarchies in eq. (23) between the g_s Yukawa couplings. In third quantization models it is possible to extend the concept of family to the gauge bosons through the semidirect product of a gauge group G , with the group of the permutation of n objects, namely $G^n \rtimes S_n$. In Ref. [11] it has been proposed a $E_6^4 \rtimes S_4$ model where E_6 is the grand unified gauge group and S_4 is the permutation symmetry of four objects. It is showed that embedding $S_3 \subset S_4$ it is possible to better explain neutrino oscillation, while E_6^4 could be useful in order to understand the hierarchies between the g_s couplings reported in eq. (23). It is presented a possible breaking pattern of $E_6^4 \rtimes S_4$ in agreement with our montecarlo results. In the following we report such a breaking pattern.

Assume that the starting group $E_6^4 \rtimes S_4$ is broken into the group $G_1 = (SM \times U(1)_r \times U(1)_t)^4 \triangleright \triangleleft S_4$ where $U(1)_r$ and $U(1)_t$ are defined as $E_6 \supset SO(10) \times U(1)_t \supset SU(5) \times U(1)_r \times U(1)_t$ and SM is the Standard Model gauge group. At some scale M_1 the group G_1 breaks into the group $G_2 = (SM \times U(1)_r \times U(1)_t)^3 \triangleright \triangleleft S_3$. It is easy to see that the only operators compatible with G_2 are

$$g \bar{d}_L^i d_R^i H \phi_i.$$

The coupling g will be of order of magnitude $g \simeq M_1/\Lambda$ where Λ is the characteristic scale of $E_6^4 \rtimes S_4$. At another scale $M_2 < M_1$ the group G_2 breaks into $G_3 = (SM \times U(1)_{\text{down}})^3 \triangleright \triangleleft S_3$ where $U(1)_{\text{down}}$ is defined as the linear combination of $U(1)_r$ and $U(1)_t$ so that right-handed down quarks do not carry $U(1)_{\text{down}}$ charge. At this scale also the operators

$$\sum_{i,j} g_L \bar{d}_L^i d_R^j H^i \phi_j$$

are allowed and $g_L \simeq M_2/\Lambda$. If $M_1 \sim M_2$ it is possible to explain the relation $g \simeq g_L$ in eq. (23). At the scale M_2 the operators proportional to g_2^d , g_3^d and g_R^d are not allowed. They only appear after the breaking of $U(1)_{\text{down}}$ at some scale $M_3 < M_2$. If $M_2 \gg M_3$ we can explain the hierarchy $g_L^d \gg g_3^d, g_R^d, g_2^d$.

Acknowledgments

I would like to thank F. Caravaglios for the helpful discussion and G. Altarelli for the useful suggestions.

 - [12] Namely, assuming that the Higgs field belong to the **1** symmetric (with respect the Z_2 parity symmetry) representation of S_3 is equivalent to study the $S_3 \times Z_2$ group.
 - [13] The $|g|$ of the complex constant g can be reabsorbed in $\langle \phi_i \rangle$ and its phase is unphysical.

- [14] There are two possibilities, namely the up quark mass matrix can be symmetric (first possibility) or antisymmetric (second possibility), while the down quark mass matrix is always antisymmetric. The first possibility is in agreement with SU(5) unification expectations. In fact it is not difficult to show that SU(5) invariance implicates $g_L^u = g_R^u$.
